# RongOS — 一个简单操作系统的设计与实现

蒲启元

(西南林业大学 大数据与智能工程学院, 云南昆明 650224)

**摘 要:** 操作系统管理着计算机的硬件和软件资源, 它是向上层应用软件提供服务(接口)的核心系统软件, 这些服务包括进程管理, 内存管理, 文件系统, 网络通信, 安全机制等。操作系统的设计与实现则是软件工业的基础。为此, 在国务院提出的《中国制造 2025》中专门强调了操作系统的开发<sup>[1]</sup>。但长期以来, 操作系统核心开发技术都掌握在外国人手中, 技术受制, 对于我们的软件工业来说很不利。本项目从零开始设计开发一个简单的操作系统, 包括 boot loader, 中断, 内存管理, 图形接口, 多任务等功能模块, 以及能运行在这个系统之上的几个小应用程序。尽管这个系统很简单, 但它是自主开发操作系统的一次尝试。

**关键词:** 操作系统, 进程, 内存, 中断, boot loader

# RongOS — A simple OS implementation

Qiyuan PU

School of Big Data and Intelligence Engineering  
Southwest Forestry University  
Kunming 650224, Yunnan, China

**Abstract:** Operating system manages the hardware and software resources in a running computer system. It is the core of any modern software system and provides services (interfaces) to upper layer applications. The services it provides include process management, memory management, file system, network communication, security mechanism and more. Operating system development is the foundation and core of software industry. Therefore, *Made in China 2025* emphasizes the development of operating system that put forward by The State Council of China. For long time, however, the OS kernel development technology is dominated by foreigners. This technical limitation is detrimental to the development of our software industry. In this project, we presents a simple operating system which includes a boot loader, interrupt services, memory management functions, a graphic interface, and multi-process management functions. Also, some trivial user-level applications are provided for system testing purpose. This simple toy OS is an experimental trial for developing an operating system from scratch.

**Key words:** operating system, boot loader, interrupt, process management, memory management

# 1 Introduction

This section will introduce the purpose and current status of the operating system research. The setup of the development environment will also be presented here.

## 1.1 Background

Contemporary software systems are beset by problems that create challenges and opportunities for broad new OS research. There are five areas could improve user experience including dependability, security, system configuration, system extension, and multiprocessor programming.

The products of forty years of OS research are sitting in everyone's desktop computer, cell phone, car, etc., and it is not a pretty picture. Modern software systems are broadly speaking complex, insecure, unpredictable, prone to failure, hard to use, and difficult to maintain. Part of the difficult is that good software is hard to write, but in the past decade, this problem and more specific shortcomings in systems have been greatly exacerbated by increased networking and embedded systems, which placed new demands that existing architectures struggled to meet. These problems will not have simple solutions, but the changes must be pervasive, starting at the bottom of the software stack, in the operating system.

The world needs broad operating system research. Dependability, security, system configuration, system extension, and multi-processor programming illustrate areas where contemporary operating systems have failed to meet the software challenges of the modern computing environment<sup>[2]</sup>.

## 1.2 Preliminary Works

### 1.2.1 Development Environment

**OS platform:** Debian 9, Linux kernel 4.12.0-1-amd64

**Editor:** GNU Emacs 25.2.2

**Run time VM:** QEMU emulator 2.8.1

**Assembler:** Nask

**Compiler:** CC1(Based on gcc)

**Debugger:** GNU gdb 7.12

**Version Control:** git 2.15

## 1.2.2 Tools

Some tools were used to develop RongOS, See *tools*<sup>1</sup>. Note that these tools are Windows executable. Please install wine if you want to run these tools on Linux. In these tools, the most important ones are:

**nask.exe:** the assembler, a modified version of NASM<sup>[3]</sup>

**cc1:** the C compiler

## 1.2.3 Platform Setup

The development platform (mainly the Debian system) was set up by following the *Debian Installation tutorial*<sup>2</sup>. The main steps include:

1. Installing the base Debian system;
2. Installing necessary software tools, such as emacs, web browser, qemu, wine, etc.;
3. Cloning configuration files by following the tutorial mentioned above;
4. Some more fine tweaks to satisfy my personal needs.

### Qemu

QEMU is a generic and open source machine emulator and virtualizer<sup>[4]</sup>. In this project, QEMU was used as the test bed.

Installing QEMU for my x86\_64 architecture can be easily done by executing the following command:

```
$ sudo apt-get install qemu-system-x86_64
```

---

<sup>1</sup>[https://github.com/Puqiyuan/RongOS/tree/master/z\\_tools](https://github.com/Puqiyuan/RongOS/tree/master/z_tools)

<sup>2</sup>[http://cs2.swfc.edu.cn/~wx672/lecture\\_notes/linux/install.html](http://cs2.swfc.edu.cn/~wx672/lecture_notes/linux/install.html)

### **Wine**

Wine (originally an acronym for “Wine Is Not an Emulator”) is a compatibility layer capable of running Windows applications on several POSIX-compliant operating systems, such as Linux, macOS, and BSD<sup>[5]</sup>.

Because the tools I used in this project are in Windows executable format, so on Debian system, Wine is needed to be installed:

```
$ sudo apt-get update
$ sudo apt-get install wine
```

### **Debian i386 support**

On 64-bit systems you need to enable multi-arch support for running 32-bit Windows applications (many modern apps are still 32-bit, also for large parts of the Windows subsystem itself). Our development tools were 32-bit Windows applications, so we needed to have i386 support for our 64-bit Linux system.

```
$ sudo dpkg --add-architecture i386
$ sudo apt-get update
```

## 2 Design

This chapter describes the design issues in the entire software system, including system startup, the kernel, APIs, and some applications.

### 2.1 Top Level Design

As shown in Fig. 2-1 shown, all applications require services from the operating system through a set of function calls. This set of functions provided by the OS kernel is usually called *system calls*. However, the user applications do not invoke these system calls directly. Instead, they call the API library functions. The process in which the API invokes a system call and hands over processing to the kernel is called *trapping*.

Within the kernel, there are some important software modules working to keep the system running well. The process control subsystem provides graphics processing, CPU scheduling, and memory management functions for processes. **Fixme: do you have VFS?** **Fixme!** The file subsystem provides a friendly way to the user processes for accessing disk data. For example, to launch an application program stored on the disk, the function in the file system must be invoked to find the specific application. All of these subsystems may interact with the driver or hardware control module so as to operate on the system hardwares.

### 2.2 Detailed Design

This section discusses the system design in details, including the function of each module, data structures used in boot loader, kernel, API, and APPs.

#### 2.2.1 Boot Up

At this stage the boot loader loads the operating system kernel into memory. This is done in the following four steps:

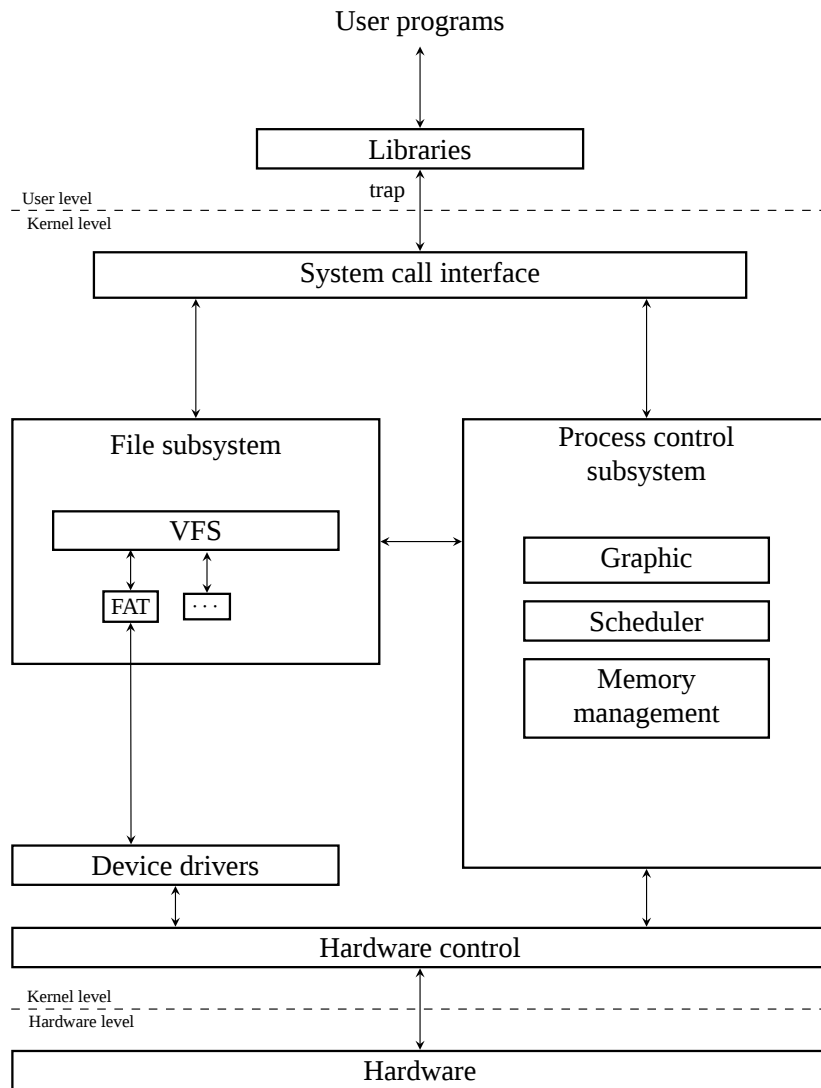

Fig. 2-1 Top-level design

1. Display boot information;
2. Read the second sector;
3. Read two sides of a track;
4. Read the next cylinder until all twenty cylinders have been read.

At this stage, it is also necessary to complete the 32-bit protection mode switch and jump to the entry point of the operating system.

### 2.2.2 Kernel

The kernel receives the API calls from user processes, and operates the hardwares through the device drivers. **Fixme: say some more.**

**Fixme!**

#### Memory Management

The process may request memory space while running. When it is finished running, the operating system kernel shall reclaim its memory space. **Fixme: say some more. you can get some ideas from wikipedia.**

**Fixme!**

#### Data Structures used in MM

```

1 struct FREEINFO
2 {
3     unsigned int addr; /* start address of free space */
4     unsigned int size; /* size of free mem in bytes*/
5 };

```

- is used to record the size in bytes of free memory while the system is running.

```

1 struct MEMMAN
2 {
3     int frees;    /* free memory blocks */
4     int maxfrees; /* max of frees */
5     int lostsize; /* release the sum of the failed memory size ?????????*/
6     int losts;    /* number of failures */
7     struct FREEINFO free[MEMMAN_FREES]; /* free memory block info */
8 };

```

- is used to record the entire memory usage, such as the total remaining free memory space and **entries** **Fixme: ???.**

**Fixme!**

## Memory Management Functions

```
1 void memman_init(struct MEMMAN* man);
```

- The memory space is initialized and the man variable is used to record the memory space usage and free information.

```
1 unsigned int memman_total(struct MEMMAN* man);
```

- Report the sum of all empty space. Return the size of free memory.

```
1 unsigned int memman_alloc(struct MEMMAN *man, unsigned int size);
```

- Allocate memory to the application, where size is the space requested by the application. Success returns the available starting address, otherwise 0.

```
1 int memman_free(struct MEMMAN *man, unsigned int addr, unsigned int size);
```

- Releases memory, where addr is the starting address variable and size is the size of the release variable. Returns 0 if successful, otherwise -1.

```
1 unsigned int memman_alloc_4k(struct MEMMAN *man, unsigned int size);
```

- Memory is allocated in 4k memory units and the starting address of the allocated memory is returned. size is the size of requested space.

```
1 int memman_free_4k(struct MEMMAN *man, unsigned int addr, unsigned int  
↪ size);
```

- Memory space is freed in units of 4k, addr is the starting point variable, and size is the release size.

## Task Management (Scheduler)

The general operating systems need to be able to support multitasking. Simply saying that multi-tasking is running multiple programs at the same time. But this only gives the user an illusion. For a single CPU, it cannot handle multiple programs at the same time. It merely divides the CPU time into many small pieces for different programs to run. The operating

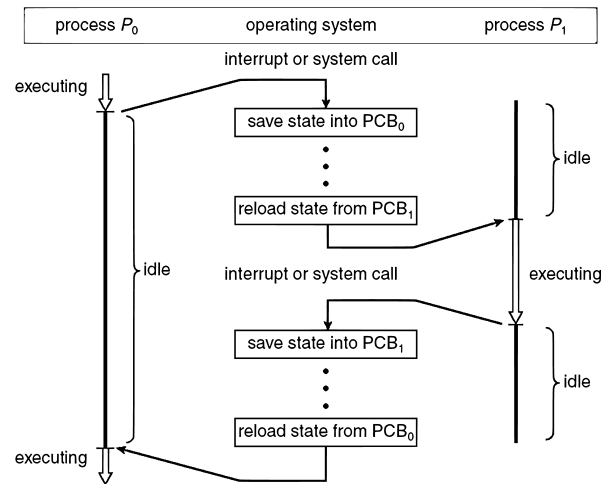

Fig. 2-2 Context switch

system should be able to do task switching, that is to pass the CPU from one process to another. And at a later time to switch it back, as shown in Fig. 2-2. Therefore, the register values should be saved when the task is switched. The task switching itself also takes time. The operating system should try to shorten this time. Doing this on the one hand provides the user with a good experience and does not leave the user with a delayed impression. On the other hand, reducing this time can improve CPU utilization. Because this time can not be used for program operation. Fixme: see wikipedia

### Data Structures For Task Management

```

1 struct TASKLEVEL
2 {
3     int running; /* how many tasks are running */
4     int now;      /* which task is currently running */
5     struct TASK* tasks[MAX_TASKS_LV]; /* all tasks in one level */
6 };
    
```

- is used to record the status of each task in a layer Fixme: What's a layer/level?.

Fixme!

```

1 struct TSS32
2 {
3     int esp0, esp1, esp2; /* stack pointer register */
4     int ss0, ss1, ss2;    /* stack segment register */
5     int cr3;             /* control register */
6     int eip;             /* instruct pointer register */
7     int eflags;          /* registers flag */
8     int eax;             /* accumulator register */
9     int ecx;             /* counter register */
10    int edx;             /* data register */
11    int ebx;             /* base register */
12    int esp;             /* stack pointer register */
13    int ebp;             /* base pointer register*/
14    int esi;             /* source index register */
15    int edi;             /* destination index register */
16    int es;              /* extra segment register */
17    int cs;              /* code segment register */
18    int ss;              /* stack segment register */
19    int ds;              /* data segment register */
20    int fs;              /* segment part 2 */
21    int gs;              /* segment part 3 */
22    int ldtr;            /* LDT segment selector */
23    int iomap;           /* I/O map base address */
24 };

```

- holds information about task status segments, which are based on CPU specifications<sup>[6]</sup>.

```

1 struct TASKCTL
2 {
3     int now_lv;         /* current activity level */
4     int lv_change;      /* does the hierarchy need to be changed next time the
5                          ↪ task is switched */
6     struct TASKLEVEL level[MAX_TASKLEVELS]; /* all levels*/
7     struct TASK tasks0[MAX_TASKS];          /* all running program */
8 };

```

- is used to control all tasks in the system. **Fixme: not clear.**

**Fixme!**

```

1 struct TASK
2 {
3     int sel;           /* the number of GDT */
4     int flags;         /* the state of task */
5     int level;         /* the level of task */
6     int priority;      /* the priority of task */
7     struct FIFO32 fifo; /* a fifo buffer */
8     TSS32 tss;         /* TSS segment for a task */
9     struct CONSOLE* cons; /* the console window address of task */
10    int ds_base;        /* data segment address of APPs */
11    int cons_stack;     /* the stack address of APPs */
12    struct SEGMENT_DESCRIPTOR ldt[2]; /* tow LDT segments of task */
13    struct FILEHANDLE* fhandle; /* file handles for manipulating files */
14    int* fat; /* file allocation table */
15    char* cmdline; /* store the command line context */
16    unsigned char langmode; /* which font to use */
17    unsigned char langbyte1; /* store the first byte of the full-width
    ↪ character */
18 };

```

- is used to manage variables for a task. Record the task's sections, permissions, stacks, etc.

### Task Management Functions

```

1 struct TASK *task_now(void);

```

- Returns which level of which task is currently running.

```

1 struct TASK *task_init(struct MEMMAN *memman);

```

- Initialize a task.

```

1 struct TASK *task_alloc(void);

```

- Initialize the structure of a task.

```

1 void task_run(struct TASK *task, int level, int priority);

```

- Add a task to list.

```

1 void task_switch(void);

```

- Switch to the next task.

```

1 void task_sleep(struct TASK *task);

```

- Put a task to sleep.

## Graphic Management

The patterns on the screen belong to one layer. The movement of the window is achieved through layers **Fixme: ???**. The height of the layer affects the layout of the screen. **Layers to consider how to cover when moving, which one is on and below. Fixme: bad** **Fixme!** **Fixme!**

## Graphic Management Data Structures

```

1 struct SHEET
2 {
3     char* buf;    /* address of the graphic content depicted */
4     int bxsize;   /* size of x coordinate of sheet */
5     int bysize;   /* size of y coordinate of sheet */
6     int vx0;      /* x coordinate of sheet */
7     int vy0;      /* y coordinate of sheet */
8     int col_inv;  /* number of invisible color */
9     int height;   /* height of sheet */
10    int flags;    /* states of sheet, using or not */
11 };

```

- is used to record layer-related information, including the layer's size and position.

```

1 struct SHTCTL
2 {
3     unsigned char* vram; /* the address of VRAM */
4     unsigned char* map;  /* which layer the pixel on the screen belongs to */
5     int xsize; /* the x size of screen */
6     int ysize; /* the y size of screen */
7     int top;   /* the height of the top layer */
8     struct SHEET* sheets[MAX_SHEETS]; /* order all layer addresses in order
    ↪ */
9     struct SHEET sheets0[MAX_SHEETS]; /* all layers */
10 };

```

- is used to manage the structure of multiple layer information, including how many layers there are in total, the size and height of each layer.

## Graphic Management Functions

```

1 struct SHTCTL *shtctl_init(struct MEMMAN *memman, unsigned char *vram, int
    ↪ xsize, int ysize);

```

- Initialize a sheet control structure, vram is the address of video RAM. xsize and ysize is the size of sheet.

```
1 struct SHEET *sheet_alloc(struct SHTCTL *ctl);
```

- Return a SHEET structure if success, otherwise 0.

```
1 void sheet_setbuf(struct SHEET *sht, unsigned char *buf, int xsize, int
↪ ysize, int col_inv);
```

- Set the properties of the layer buf.

```
1 void sheet_updown(struct SHEET *sht, int height);
```

- Set the height of layer sht.

```
1 void sheet_refresh(struct SHEET *sht, int bx0, int by0, int bx1, int by1);
```

- Refreshes the screen range specified by bx0, by0, bx1 and by1.

```
1 void sheet_free(struct SHEET *sht);
```

- Release layer.

```
1 void make_window8(unsigned char *buf, int xsize, int ysize, char *title,
↪ char act);
```

- Make a window in SHEET buf.

```
1 void putfonts8_asc_sht(struct SHEET *sht, int x, int y, int c, int b, char
↪ *s, int l);
```

- Paint the background color and write the characters and finish the refresh.

### System Calls

The system calls encapsulate each module in the kernel **Fixme: ???**. These system **Fixme!** calls are part of the kernel. In this system, system calls are called by the API instead of the application. **Fixme: see wikipedia** **Fixme!**

### System Calls Prototype

```
1 void cons_putchar(struct CONSOLE *cons, int chr, char move);
```

- put a chr character on cons console.

```
1 void cons_newline(struct CONSOLE *cons);
```

- newline in cons console.

```
1 void cons_putstr0(struct CONSOLE *cons, char *s);
```

- put string s in cons console, no length.

```
1 void cons_putstr1(struct CONSOLE *cons, char *s, int l);
```

- put string s in cons, l is the length of string s.

```
1 int cmd_app(struct CONSOLE *cons, int *fat, char *cmdline);
```

- Start an application based on the input from the command line cmdline;

### Driver

The device drivers are used to control and manipulate the hardware. [The driver blocked the hardware information](#) Fixme: wikipedia. It is the dividing line between hardware and software. A driver provides a software interface to hardware devices, enabling operating systems and other computer programs to access hardware functions without needing to know precise details of the hardware being used.

### Driver Functions

```
1 void set_palette(int start, int end, unsigned char *rgb);
```

- initialize the palette.

```
1 void init_pic(void);
```

- initialize the PIC.

```
1 void init_keyboard(struct FIFO32 *fifo, int data0);
```

- initialize the keyboard.

```
1 void enable_mouse(struct FIFO32 *fifo, int data0, struct MOUSE_DEC *mdec);
```

- activate mouse.

### FAT File System

The file system defines how data is stored and accessed. The file system divides the entire storage space according to a certain form. This facilitates the storage of files while increasing the utilization of storage media. The small blocks thus divided are called sectors. The FAT records which sectors all files are stored on. Fixme: wikipedia

### FAT Data Structure

```
1 struct FILEINFO
2 {
3     unsigned char name[8];    /* file name */
4     unsigned char ext[3];    /* extend name of file */
5     unsigned char type;      /* file attributes */
6     char reserve[10];        /* reserve byte */
7     unsigned short time;     /* the time for storing file */
8     unsigned short date;     /* the date for storing file */
9     unsigned short clustno; /* the file from which sector on the disk is
    ↪ stored */
10 };
```

- is used to record file-related information, such as file name, size, etc.

### FAT Functions

```
1 void file_readfat(int *fat, unsigned char *img);
```

- read file allocation table

```
1 void file_loadfile(int clustno, int size, char *buf, int *fat, char *img);
```

- read file contents into memory

```
1 struct FILEINFO *file_search(char *name, struct FILEINFO *finfo, int max);
```

- search for files based on provided name.

### 2.2.3 API

In computer programming, APIs are subroutines that are used to develop applications. Usually, it communicates all parts of the software. A good API makes application development easier. By abstracting the underlying implementation and only exposing objects or actions the developer needs, an API simplifies programming.

#### All APIs

```
1 void api_putchar(int c);
```

- output a character `c` on the console window.

```
1 void api_putstr0(char *s);
```

- output a string `s` on the console window.

```
1 void api_putstr1(char *s, int l);
```

- output a string `s` on console window, `l` is the length of this string.

```
1 void api_end(void);
```

- end the application's running.

```
1 int api_openwin(char *buf, int xsiz, int ysiz, int col_inv, char *title);
```

- open a window, return the handler of window.

```
1 void api_putstrwin(int win, int x, int y, int col, int len, char *str);
```

- display string `str` on window.

```
1 void api_boxfilwin(int win, int x0, int y0, int x1, int y1, int col);
```

- draw a box on the window

```
1 void api_initmalloc(void);
```

- initialize the structure of the management memory

```
1 char *api_malloc(int size);
```

- allocating memory for the application.

```
1 void api_free(char *addr, int size);
```

- free up memory used by the application.

```
1 void api_point(int win, int x, int y, int col);
```

- draw a pint on win window.

```
1 void api_refreshwin(int win, int x0, int y0, int x1, int y1);
```

- refresh the window.

```
1 void api_linewin(int win, int x0, int y0, int x1, int y1, int col);
```

- draw a straight line.

```
1 void api_closewin(int win);
```

- close window.

```
1 int api_getkey(int mode);
```

- accept keyboard input.

```
1 int api_alloctimer(void);
```

- get timer.

```
1 void api_inittimer(int timer, int data);
```

- set the data of timer sending.

```
1 void api_settimer(int timer, int time);
```

- set the time of timer.

```
1 void api_freetimer(int timer);
```

- release timer.

```
1 void api_beep(int tone);
```

- make a buzzer sound

```
1 int api_fopen(char *fname);
```

- open file, return file handler

```
1 void api_fclose(int fhandle);
```

- close file

```
1 void api_fseek(int fhandle, int offset, int mode);
```

- locate a file

```
1 int api_fsize(int fhandle, int mode);
```

- return the size of fhandle file.

```
1 int api_fread(char *buf, int maxsize, int fhandle);
```

- read file, return read bytes.

```
1 int api_cmdline(char *buf, int maxsize);
```

- return the context of command line.

```
1 int api_getlang(void);
```

- return the language mode.

## 2.2.4 APPs

Since this design is only about the operating system itself, only three representative applications are introduced. The first is the application of the display color: `color`. The second is the application for timing: `sundial`. The third application is to imitate the application of stars in the sky: `stars2`.

## 3 Implementation

### 3.1 Boot Up

The boot loader is implemented in Intel assembly. It works as follows:

1. **Display boot information:** Firstly, the code in boot sector (See Appendix A.1.1) outputs some boot information. When `al=0`, the null character of boot information hit. Fixme! Interrupt `0x10` is used for showing a character on the screen. Fixme: Not clear. You have to explain what is `al/ah` for. For example, as shown in table... `al` is for..., `ah` is for... int `0x10` is for...
2. **Read the second sector:** Then jump to load `C0-H0-S2`, `ax` register saved the address where beginning puts the sectors from floppy. And preparing parameters for interrupt `0x13` in registers. The `0x13` interrupt used for read sector from floppy to memory. (See Appendix A.1.2).
3. **Read two sides of a track:**

If there is a carry indicating some thing went wrong while reading the floppy disk, reset the registers and try reading it again. The read process aborts after five unsuccessful read.

Register `si` is a counter. If no carry (success), jump to next segment, as one sector has been read into memory already. The address should increase 512 byte. Then sector number (`cl` register) is added by 1 and compare it to 18, if it's smaller than 18, jump to `readloop`, read the next sector.

If the value of `cl` register is bigger or equal to 18, meaning that one track 18 sector in this side of floppy read already, then reversed the head, add 1 to `dh` register.

If the value of `dh` register after adding larger than or equal to 2, it's saying the original head is 1, one track of two sides read already. Otherwise the value of `dh` register smaller than 2, read this side indicating by `dh` register, jump to `readloop` segmentation.

Appendix A.1.3 is the code performing this function.

There is a pseudo code about this process:

```

Result: Read two sides of one track
1 ENTRANCE: call readloop();
2 Procedure readloop()
3   clear the times of failed to 0,  $si \leftarrow 0$ ;
4   call retry();
5 Procedure retry()
6   register parameter preparing;
7   read a sector;
8   if no carry then
9     call next();
10  else
11    add 1 to si,  $si \leftarrow si + 1$ ;
12    compare si with 5;
13    if  $si \geq 5$  then
14      goto error, FINISHED;
15    else
16      reset registers and call retry() to read again;
17    end
18  end
19 Procedure next()
20   memory address moved back 0x200;
21   add 1 to cl, preparing for reading the next sector,  $cl \leftarrow cl + 1$ ;
22   if  $cl \leq 18$  then
23     call readloop() to read this sector;
24   else
25      $cl > 18$ , it means that one side of this track is read already;
26     add 1 to dh,  $dh \leftarrow dh + 1$ , reverse the head pointer;
27     if  $dh < 2$  then
28       it means the 1 side has not read yet, call readloop();
29     else
30       both sides have finished reading, FINISHED;
31     end
32   end

```

**Algorithm 1:** read two sides of one track

4. **The next cylinder:** So the next step is moving a cylinder, add 1 to register ch. Otherwise the value of dh register smaller than 2, read this side indicating by dh register, jump to readloop segmentation. After ch register add 1, if it's smaller than 10, jump to readloop, otherwise end loading floppy to memory process, for we only load ten cylinders of floppy. Appendix A.1.4 is the code to perform this function.

The above four steps can be intuitively reflected in the Fig. 3-1.

## 4 Conclusions

**What goes in your “Conclusions” chapter?** The purpose of this chapter is to provide a summary of the whole thesis or report. In this context, it is similar to the Abstract, except that the Abstract puts roughly equal weight on all thesis/report chapters, whereas the Conclusions chapter focuses primarily on the findings, conclusions and/or recommendations of the project.

There are a couple of rules –one rigid, one common sense, for this chapter:

- All material presented in this chapter must have appeared already in the report; no new material can be introduced in this chapter. (rigid rule of technical writing)
- Usually, you would not present any new figures or tables in this chapter. (rule of thumb)

Generally, for most technical reports and Masters theses, the Conclusions chapter would be 3 to 5 pages long (double spaced). It would generally be longer in a large PhD thesis. Typically you would have a paragraph or two for each chapter or major subsection. Aim to include the following (typical) content.

1. Re-introduce the project and the need for the work –though more briefly than in the intro;
2. Re-iterate the purpose and specific objectives of your project.
3. Re-cap the approach taken –similar to the road map in the intro; however, in this case, you are re-capping the data, methodology and results as you go.
4. Summarize the major findings and recommendations of your work.
5. Make recommendations for future research.

# **Supervisor**

Xiaolin WANG (Mr.), 49 years old, got his MSc degree at University of Greenwich in UK. Currently he's been working as a lecturer at the School of Big Data and Intelligence Engineering, Southwest Forestry University in China, teaching Linux, Operating Systems, and Computer Networking.

# Acknowledgments

I would like to thank my supervisor Mr. WANG Xiaolin for his continuous support of my four years undergraduate study. I am extremely thankful to him for sharing expertise, and sincere and valuable guidance and encouragement extended to me.

What I most want to thank is my girlfriend. She tolerated me when I finished this graduation project many nights did not accompany her, gave me support, encouraged me, and did not complain. So I would like to name this simple operating system as RongOS. Rong is the last word of her name. Thank you, my dearest.

My special thanks to a great company - Google, I think I need to thank you in this very formal place in my graduation thesis. Every time you gave me a lot of help, the knowledge and other abilities I learned from you will have a profound impact on my future life. I am grateful for every search, because I know you will give me the results I want. Without you, this paper cannot be completed. Thank you.

# A Main Program Code

## A.1 Boot loader

### A.1.1 Display boot information

```
55  init:
56      mov al, [si]
57      add si, 1 ; increment by 1.
58      cmp al, 0
59      je load ; if al == 0, jmp to load, the msg_init info displayed.
60  ; the latest character is null character, coding in 0.
61
62      mov ah, 0x0e ; write a character in TTY mode.
63      mov bx, 15 ; specify the color of the character.
64      int 0x10 ; call BIOS function, video card is number 10.
65      jmp init
```

### A.1.2 Read the second sector

```
87  load:
88      mov ax, 0
89      mov ax, 0x0820 ; load C0-H0-S2 to memory begin with 0x0820.
90      mov es, ax
91      mov ch, 0 ; cylinder 0.
92      mov dh, 0 ; head 0.
93      mov cl, 2 ; sector 2.
94
95
96  readloop:
97      mov si, 0 ; si register is a counter, try read a sector
98  ; five times.
99
100
101  retry:
102      mov ah, 0x02 ; parameter 0x02 to ah, read disk.
103      mov al, 1 ; parameter 1 to al, read disk.
104      mov bx, 0
105      mov dl, 0x00 ; the number of driver number.
106      int 0x13 ; after prepared parameters, call 0x13 interrupted.
```

### A.1.3 Read two sides of a track

```
108      jnc next ; if no carry read next sector.
109      add si, 1 ; tring again read sector, counter add 1.
110      cmp si, 5 ; until five times
111      jae error ; if tring times large than five, failed.
```

```
112
113     ; reset the status of floppy and read again.
114     mov ah, 0x00
115     mov dl, 0x00
116     int 0x13
117     jmp retry
118
119
120 next:
121     mov ax, es
122     ; we can not directly add to es register.
123     add ax, 0x0020 ; add 0x0020 to ax
124     mov es, ax ; the memory increase 0x0020 * 16 = 512 byte.
125     ; size of a sector.
126     add cl, 1 ; sector number add 1.
127     cmp cl, 18 ; one track have 18 sector.
128     jbe readloop ; jump if below or equal 18, read the next sector.
129     mov cl, 1 ; cl number reset to 1, ready to read the other side.
130     add dh, 1 ; the other side of floppy.
131     cmp dh, 2 ; only two sides of floppy.
132     jb readloop ; if dh < 2, read 18 sectors of the other sides
```

### A.1.4 The next cylinder

```
134     mov dh, 0 ; after finished read the other side, reset head to 0.
135     add ch, 1 ; two sides of a cylinder readed, add 1 to ch.
136     cmp ch, CYLS ; read 10 cylinders.
137     jb readloop
```
